The Radiology Assistant Breast Calcifications

The breast contains 15-18 lobes, that each contain 20-40 lobules. The terminal ductal lobular unit is an important structure because most invasive cancers arise from the TDLU. It also is the site of origin of ductal carcinoma in situ (DCIS), lobular carcinoma in situ, fibroadenoma and fibrocystic disease, like cysts, apocrine metaplasia

Breast calcifications Radiology Reference Article

Breast calcifications are deposits of calcium salts in the breast, which are radio-opaque on mammography.. The majority are benign, but they can be associated with cancer. The ability to diagnose and appropriately manage the significant microcalcifications and differentiate them from innocuous findings is part of the art and science of breast imaging.

Understanding Breast Calcifications

The surgeon or radiologist often has to use mammography to guide a needle to the location of the calcifications, since they are too small to be felt. This is called stereotactic needle biopsy. Your breast would be numbed first with local anesthesia to minimize any discomfort.

The Radiology Assistant Breast MRI

Breast MRI is also better at monitoring the response to chemotherapy than other imaging modalities used today. It can change the treatment plan in 15-30% of patients with breast cancer. We will discuss the interpretation of breast MRI by looking at: The morphology of a lesion; T1- and T2- characteristics
